Assignment 2: Coding Basics

Sayra Martinez

OVERVIEW

This exercise accompanies the lessons in Environmental Data Analytics on coding basics.

Directions

- 1. Rename this file <FirstLast>_A02_CodingBasics.Rmd (replacing <FirstLast> with your first and last name).
- 2. Change "Student Name" on line 3 (above) with your name.
- 3. Work through the steps, **creating code and output** that fulfill each instruction.
- 4. Be sure to **answer the questions** in this assignment document.
- 5. When you have completed the assignment, **Knit** the text and code into a single PDF file.
- 6. After Knitting, submit the completed exercise (PDF file) to Sakai.

Basics, Part 1

- 1. Generate a sequence of numbers from one to 30, increasing by threes. Assign this sequence a name.
- 2. Compute the mean and median of this sequence.
- 3. Ask R to determine whether the mean is greater than the median.
- 4. Insert comments in your code to describe what you are doing.

```
#1.
kplus3_seq <- seq(1, 30, 3) ## I name and create the sequence.
kplus3_seq #I call up the sequence

## [1] 1 4 7 10 13 16 19 22 25 28

#2.
mean(kplus3_seq)

## [1] 14.5

median(kplus3_seq)
```

[1] 14.5

```
summary(kplus3_seq) # Although I used the specific computation, this function also returns the requeste
##

                              Mean 3rd Qu.
                                               Max.
##
      1.00
              7.75
                     14.50
                              14.50
                                      21.25
                                              28.00
#3.
mean(kplus3_seq) > median(kplus3_seq) #The instruction requested is this, but as it is false, below I a
## [1] FALSE
mean(kplus3_seq) < median(kplus3_seq)</pre>
## [1] FALSE
mean(kplus3_seq) == median(kplus3_seq)
## [1] TRUE
```

Basics, Part 2

- 5. Create a series of vectors, each with four components, consisting of (a) names of students, (b) test scores out of a total 100 points, and (c) whether or not they have passed the test (TRUE or FALSE) with a passing grade of 50.
- 6. Label each vector with a comment on what type of vector it is.
- 7. Combine each of the vectors into a data frame. Assign the data frame an informative name.
- 8. Label the columns of your data frame with informative titles.

```
#5. I create the vectors
Student_Name <- c("Eve", "Luis", "Silvana", "Ainah") # Character type
test_scores <- c(90, 45, 99, 50) # numeric type
passed <- test_scores >= 50 & test_scores <= 100 # logical type

#6.I determine the type of data of each vector
class(Student_Name)

## [1] "character"

class(test_scores)

## [1] "numeric"
class(passed)

## [1] "logical"</pre>
```

```
#7. I create the data frame combining the vectors.
df_scores <- as.data.frame(cbind(Student_Name,test_scores,passed))</pre>
class(df scores)
## [1] "data.frame"
#8.
names(df_scores) <- c("Student Names", "Test Scores", "Passed") #I named the columns
colnames(df scores)
## [1] "Student Names" "Test Scores"
                                         "Passed"
df_scores
##
     Student Names Test Scores Passed
## 1
               Eve
                             90
## 2
              Luis
                             45
                                FALSE
## 3
           Silvana
                             99
                                  TRUE
## 4
             Ainah
                             50
                                  TRUE
```

9. QUESTION: How is this data frame different from a matrix?

Answer: While the matrix only allows to enter data of the same type, the data frame has different types of data. In this case, it contains, character, numeric and logical information.

- 10. Create a function with an if/else statement. Your function should take a **vector** of test scores and print (not return) whether a given test score is a passing grade of 50 or above (TRUE or FALSE). You will need to choose either the **if** and **else** statements or the **ifelse** statement.
- 11. Apply your function to the vector with test scores that you created in number 5.

```
#10. I create the function
approved <- function(x){
   ifelse(x>=50 & x<=100, print(TRUE), print(FALSE))
}
#11. I apply the function "approved" for the values in my vector "test_scores"
results <- approved(test_scores)

## [1] TRUE
## [1] FALSE

print(results)

## [1] TRUE FALSE TRUE TRUE

## These other examples are for my own: approved(49)
#approved(c(48, 49, 56, 100, 101))</pre>
```

12. QUESTION: Which option of if and else vs. ifelse worked? Why?

Answer: I used "ifelse" function, because I think it was a simple logical request, since it was a binary response, but "if else" function could help me to better track my conditions in more complex cases.
